

An aerial photograph of a pumped-storage hydroelectric dam in a forested valley. The dam is a long, low concrete structure across a river. To the left of the dam is a large, circular reservoir. The surrounding landscape is covered in dense forest with autumn foliage in shades of orange, yellow, and brown. The sky is overcast and hazy. The text "Pumped-storage Hydro Technology In New Zealand" is overlaid in white, and "Ugo Mbakwe" is written in black below it.

# Pumped-storage Hydro Technology In New Zealand

Ugo Mbakwe

# Importance of Energy Storage in Modern Power Grids

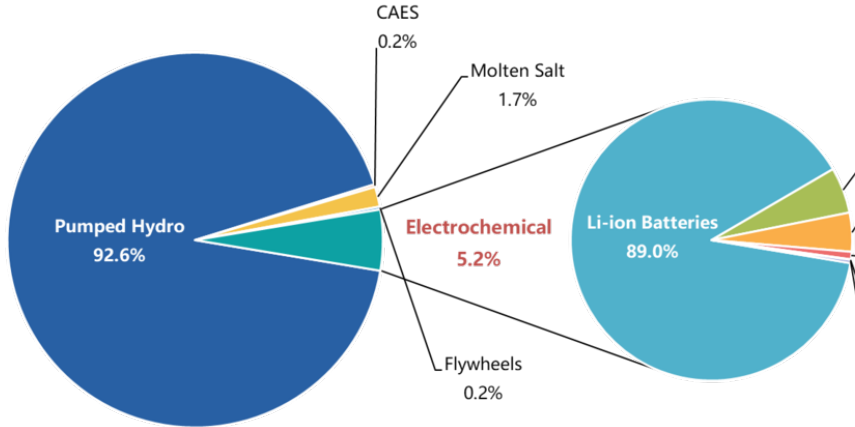

- ▶ Balancing supply and demand
- ▶ Integration of renewable energy
- ▶ Improved grid stability
- ▶ Reduced reliance on fossil fuels
- ▶ Cost savings and energy efficiency
- ▶ Emergency backup and disaster recovery

# What is Pumped-storage Hydropower?

- Pumped storage hydropower (PSH) is a type of hydroelectric energy storage.
- It is a configuration of two water reservoirs at different elevations that can generate power as water moves down from one to the other (discharge), passing through a turbine
- Two types
  - Closed loop - naturally flowing water source
  - Open-loop- without a significant natural inflow

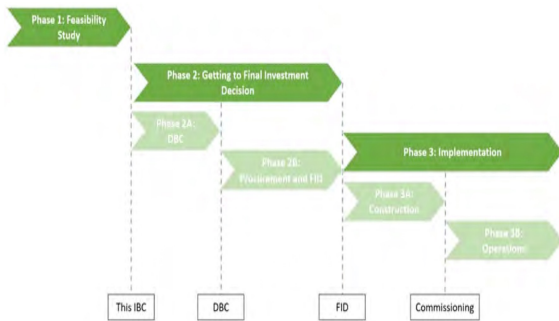

# Pumped Hydro occupies 93% of global energy storage market

► Pumped storage hydropower is the world's largest battery technology,

► Hydropower storage capacity is expected to increase by almost 50 per cent by 2030 - from 161,000 MW today to 239,000 MW

► Pumped hydro complement electrochemical batteries, they best for longer storage solution

## NZ Battery Project

This climate change initiative is investigating the ability of pumped hydro, and alternative technologies, to address New Zealand's dry year electricity problem

The project comprises of 3 phases:

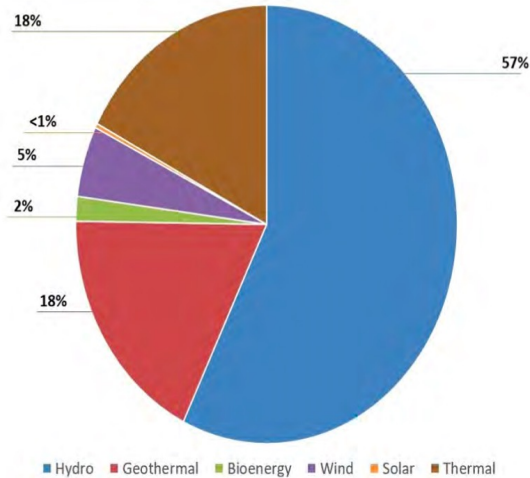

- Phase 1-feasibility study
- Phase 2 -Detailed business case, final investment decision
- Phase 3- Implementation

## The dry year problem

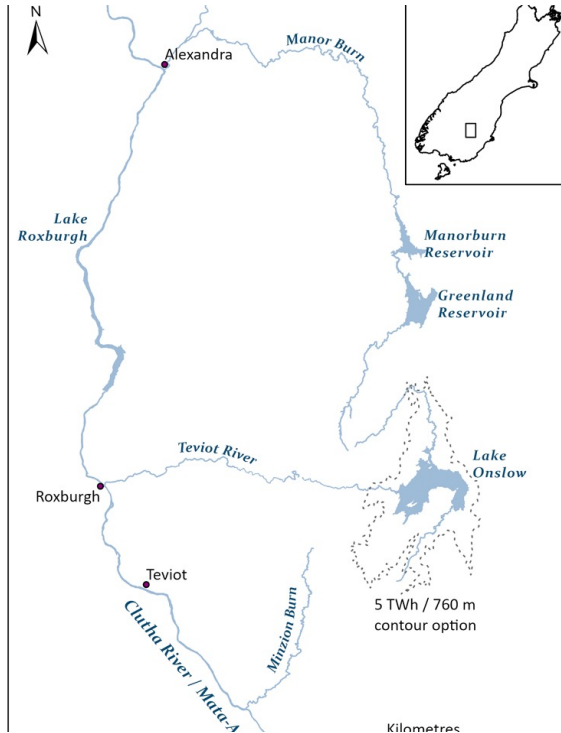

- ▶ New Zealand's 'dry year problem' is when existing hydro-power systems don't receive enough rainfall or snowmelt and the level of the storage lakes runs low. When this occurs some form of back-up is needed, and this is currently provided by fossil fuel generation.
- ▶ 'Dry years' usually last for a few months, and it's not possible to predict when one might occur, or how long it may last.
- ▶ NZ Battery Project estimates there can be an energy deficit of between 3 and 5 TWh in the worst dry years. This is about 10% of our current annual energy needs.

# Scope of the NZ Battery Project

- ▶ The NZ Battery Project focuses on security of supply on the longer timescale of the dry year problem
- ▶ Evaluate the hydrology, but also ecology and to work if it is technically feasible.

# Lake Onslow

Development of pumped hydro scheme in Central Otago in the South Island. Lake Onslow is anticipated to have an upper reservoir capable of storing up to **5TWh of energy with turbines able to generate 1,000MW.**

- ▶ It is estimated to have a construction and commissioning timeframe of between 7 and 9 years.
- ▶ The estimated cost of the Lake Onslow pumped hydro scheme is about \$15.7 billion.
- ▶ 700 meters above Clutha River

## Onslow (8 TWh)

World's largest scheme  
by energy storage  
capacity

The real feature of Onslow is its  
large energy storage capacity
